#### Abstract

Brønsted acid $\mathrm{HNTf}_{2}\left(\mathrm{Tf}=\mathrm{SO}_{2} \mathrm{CF}_{3}\right)$ mediated dehydrogenative hydride abstraction from $\left(\mathrm{L}^{1}\right) \mathrm{BH}_{3}(\mathbf{3})$ and $\left(\mathrm{L}^{2}\right) \mathrm{BH}_{3}(4)\left(\mathrm{L}^{1}=\operatorname{IPrCH} 2=1,3\right.$-(2,6-di-isopropylphenyl)imidazol-2-methylidene (1); $\mathrm{L}^{2}=\operatorname{SIPrCH} \mathrm{P}_{2}=1,3-$ (2,6-di-isopropylphenyl)imidazolidin-2-methylidiene (2)) affords thermally stable hydride bridged monocationic hydrido boron compounds $\left[\left\{\left(\mathrm{L}^{1}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf} f_{2}\right)(5)$ and $\left[\left\{\left(\mathrm{L}^{2}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf}_{2}\right)(6)$. Furthermore, hydride abstraction yields di-cationic hydrido boron compounds $\left[\left\{\left(\mathrm{L}^{1}\right) \mathrm{BH}\right\}_{2}(\mu-\mathrm{H})_{2}\right]\left(\mathrm{NTf}_{2}\right)_{2}(7)$ and $\left[\left\{\left(\mathrm{L}^{2}\right)\right.\right.$ -$\left.\mathrm{BH}\}_{2}(\mu-\mathrm{H})_{2}\right]\left(\mathrm{NTf}_{2}\right)_{2}(\mathbf{8})$. Unique cationic boron compounds with $\mathrm{CH}_{2} \mathrm{BH}_{2}(\mu-\mathrm{H}) \mathrm{BH}_{2} \mathrm{CH}_{2}$ (5 and 6) and $\mathrm{CH}_{2} \mathrm{BH}\left(\mu-\mathrm{H}_{2} \mathrm{BHCH}_{2}(7\right.$ and 8$)$ moieties feature a $3 \mathrm{c}-2 \mathrm{e}$ bond and have been fully characterized. Interesting electronic and structural features of compounds 5-8 are analysed using spectroscopic, crystallographic, and computational methods.

## Introduction

Investigation of thermally stable exotic main group compounds with elusive chemical and electronic properties has been a subject of considerable research interest. ${ }^{1}$ Boron compounds play an important role in organic synthesis and materials science. ${ }^{2}$ The search for new boron compounds with unique bonding motifs and electronic structures has been a major focus in molecular main group chemistry. ${ }^{3}$ A variety of mono-cationic boron compounds such as borinium $\left[\mathrm{R}_{2} \mathrm{~B}\right]^{+}$, borenium $\left[(\mathrm{L}) \mathrm{R}_{2} \mathrm{~B}\right]^{+}$, and boronium $\left[(\mathrm{L})_{2} \mathrm{R}_{2} \mathrm{~B}\right]^{+}$species $(\mathrm{L}=\mathrm{a}$ neutral ligand) have been isolated and characterized. ${ }^{2 c, 4}$ Recent studies have demonstrated a remarkable activity of borenium compounds in Lewis acid catalysis as well as in the functionalization of small molecules. ${ }^{2 c, 5}$ Interestingly, so far only a few di-cationic boron compounds, in particular with a hydride ligand, have been isolated and adequately characterized (Scheme 1). ${ }^{4 c, 6}$

[^0]

A

D

Scheme 1 Di-cationic hydrido boron compounds A-D.

Cowley et al. reported the first hydrido boron di-cation (A) stabilized by a pyridine ligand (Scheme 1$).{ }^{6 f}$ A direct B-B coupling reaction of a mono-cationic species to afford a di-cationic boron compound (B) stabilized by a cyclic guanidine ligand has been recently described by Himmel and co-workers. ${ }^{4 c}$ Singlet carbenes have been recognized as most suitable candidates for taming highly reactive main group species. ${ }^{3 n, 7}$ Therefore, boryl radicals, ${ }^{3 r, 8}$ borenium ions, ${ }^{4 e, 5 a, d, 6 b, 9}$ boryl anions, ${ }^{2 e, 3 i, q, s, 10}$ borylenes, ${ }^{3 e, o, 7 b, 11}$ diborene, ${ }^{3 g, 12}$ and diboryne ${ }^{3 k}$ compounds have been successfully isolated by using

Scheme 2 Synthesis of NHO-borane compounds 3 and 4.

N-heterocyclic carbenes (NHCs). Curran et al. employed an NHC and isolated a hydride-bridged boron di-cation (C). ${ }^{6 b}$ A carbodicarbene stabilized hydrido boron di-cation (D) has been reported very recently by Ong and co-workers. ${ }^{6 a}$

While the flanking substituents at the imidazole nitrogen atoms of an NHC are well endowed to encapsulate a reactive species to be stabilized, but they may prevent its accessibility for further reactions. ${ }^{3 n, 13}$ Moreover, NHC-coordinated main group species sometimes do not exhibit the expected reactivity owing to the diminished electrophilicity. This is due to the strong NHC-element interaction. To circumvent this situation and to expand the scope of reactive main group species to functionalize organic substrates, we became interested in the new class of carbon-donor ligands. ${ }^{14} \mathrm{~N}$-Heterocyclic olefins (NHOs) and their borane adducts were already known as early as in 1993, ${ }^{15}$ interest in this class of ligands incited us very recently. ${ }^{16}$ NHOs (1 and 2, Scheme 2) are strong nucleophiles but rather weak electron donors (Lewis bases) than NHCs. ${ }^{17}$ Therefore, NHOs readily react with a NHC-stabilized dichlorosilylene ( IPr ) $\mathrm{SiCl}_{2}$ to furnish silyl-functionalized NHOs and liberate free $\operatorname{IPr}(\operatorname{IPr}=1,3-(2,6$-di-isopropylphenyl)imidazol-2ylidene). ${ }^{18}$ Similarly, $\mathrm{KC}_{8}$ reduction of (NHO)BRX ${ }_{2}$ ( $\mathrm{R}=\mathrm{I}$ or Ph ; $\mathrm{X}=\mathrm{Cl}$ or I) compounds led to the insertion of a borylene into a C-N bond to yield boryl-functionalized NHOs. ${ }^{14 b}$ Herein, we report on a very facile route to NHO-stabilized mono- and dicationic hydrido boron compounds featuring $\left[\mathrm{CH}_{2} \mathrm{BH}_{2}(\mu-\mathrm{H})\right.$ $\mathrm{BH}_{2} \mathrm{CH}_{2}$ ] and $\left[\mathrm{CH}_{2} \mathrm{BH}(\mu-\mathrm{H})_{2} \mathrm{BHCH}_{2}\right.$ ] bonding motifs. Synthesis, characterization, reactivity, structure, and computational analysis of these compounds are presented.

## Results and discussion

The reaction of an NHO ( $\mathrm{L}^{1}$ or $\mathrm{L}^{2}$ ) with (THF) $\mathrm{BH}_{3}$ quantitatively yields $\left(\mathrm{L}^{1}\right) \mathrm{BH}_{3}(3)$ and $\left(\mathrm{L}^{2}\right) \mathrm{BH}_{3}(4)$ as white solids $\left(\mathrm{L}^{1}=\right.$ $\mathrm{IPrCH}_{2}(\mathbf{1})$ and $\mathrm{L}^{2}=\mathrm{SIPrCH}_{2}$ (2); $\mathrm{IPrCH}_{2}=1,3$-(2,6-di-isopropyl-phenyl)-imidazol-2-methylidene and $\mathrm{SIPrCH}_{2}=1,3$-(2,6-di-isopropylphenyl)imidazolidin-2-methylidiene) (Scheme 2). Treatment of compounds 3 and 4 with 0.5 eq. of bis(trifluoromethane)sulfonimide $\left(\mathrm{HNTf}_{2}\right)$ readily affords mono-cationic hydrido boron compounds $\left[\left\{\left(\mathrm{L}^{1}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf}_{2}\right)$ (5) and $\left[\left\{\left(\mathrm{L}^{2}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf}_{2}\right)(6)$ in a high yield (Scheme 3).

Compounds 3-6 have been characterized by ${ }^{1} \mathrm{H},{ }^{11} \mathrm{~B}$ and ${ }^{13} \mathrm{C}$ NMR as well as IR spectroscopic studies. The exocyclic methylene $\left(\mathrm{CH}_{2}\right)$ group each in $\mathbf{3}$ and $\mathbf{4}$ appears as a broad signal in

Scheme 3 Synthesis of mono- and di-cationic hydrido boron compounds 5-8.
the ${ }^{1} \mathrm{H}$ NMR spectrum at $\delta 1.60$ and $\delta 1.41 \mathrm{ppm}$, respectively. Each of compounds $5(\delta-15.4)$ and $6(\delta-16.4)$ exhibits a broad ${ }^{11} \mathrm{~B}$ NMR signal, which is shifted towards downfield (ca. 14 ppm ) when compared with the respective starting compound $3(\delta-29.9)$ or $4(\delta-29.5)$. Moreover, the ${ }^{11} \mathrm{~B}$ NMR chemical shift, each for 5 and $\mathbf{6}$, is $c a .10 \mathrm{ppm}$ downfield compared to NHC-analogues. ${ }^{6 b}$ This may be due to the lower basicity of $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ ligands than that of NHCs. Nevertheless, compounds 5 and 6 are stable both in solution $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$, $\mathrm{CHCl}_{3}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$, and $1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}$ ) and solid phases at room temperature under an inert gas ( Ar or $\mathrm{N}_{2}$ ) atmosphere.

Suitable single crystals for X-ray diffraction study were obtained by a slow diffusion of $n$-hexane into a saturated dichloromethane solution of 5 at room temperature. The solidstate structure of 5 revealed the formation of a hydride bridged mono-cationic boron compound (Fig. 1). The B-( $\mu-\mathrm{H})-\mathrm{B}$ bond is apparently derived from a 3c-2e (three-center-two-electrons) interaction. The $C(0)-B(0)$ bond length of $1.630 \AA$ in 5 is slightly shorter than that of $4(1.68 \AA)$. The $\mathrm{C}(0)-\mathrm{C}(1)$ bond lengths of $4(1.452 \AA)$ and $5(1.467)$ are comparable with $\mathrm{C}\left(\mathrm{sp}^{2}\right)-\mathrm{C}\left(\mathrm{sp}^{3}\right)$ single bond distances. All hydrogen atoms near the boron atom were located on difference Fourier maps and refined isotropically as independent atoms. Due to experimental restrictions, all B-H distances are underestimated. The electron density of hydrogen is always shifted towards the bonding partner and due to the lack of core electrons, a shortened B-H bond length is obtained in the IAM refinement. ${ }^{19}$

In order to shed light into the electronic structures, we carried out DFT calculations (M06-2X/def2-SVP) ${ }^{20}$ for 5 and 6. The optimized bond lengths and angles of 5 are in good agreement with the experimental values (Fig. 1). A comparison of the calculated structures of 5 and 6 indicates (Fig. S2 in the ESI $\ddagger$ ) very similar geometries for the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{H}-\mathrm{BH}_{2}$ moiety. Compound 6 presents a slightly longer $\mathrm{B}-\mu \mathrm{H}$ bond length and more acute $\mathrm{C}_{\text {(carbene) }}{ }^{-} \mathrm{C}-\mathrm{B}$ angles than those in 5. Based on the natural population analysis ${ }^{21}$ (Table 1) the boron fragment $\mathrm{B}_{2} \mathrm{H}_{5}$ is negatively charged by -0.23 e and -0.20 e for $\mathbf{5}$ and $\mathbf{6}$,

Fig. 1 (a) Molecular structure of compound 5. Hydrogen atoms except those on the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{H}-\mathrm{BH}_{2}$ moiety, isopropyl groups, and the anionic part have been omitted for clarity. Thermal ellipsoids are represented at the $50 \%$ probability level. Boron bound hydrogen atoms were refined without restraints. respectively. Additionally, natural bond orbital (NBO) ${ }^{22}$ analysis reveals the presence of a 3c-2e bond (Tables S2 and S3 $\ddagger$ ) $\mathrm{B}-\mu \mathrm{H}-\mathrm{B}$ where $47 \%$ is at the H atom and roughly $26 \%$ on each of the boron atoms. NBO results also point out that the ligands bind boron by C-B $\sigma$-bonds which are polarized toward the carbon end ( $\sim 70 \%$ at C).

The reaction of 3 and 4 with $\mathrm{HNTf}_{2}$ in a $1: 1$ molar ratio cleanly yields di-cationic hydrido boron compounds 7 and 8 (Scheme 3) as white solids. Compounds 7 and 8 are rather poorly soluble in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}$ but are freely dissolved in acetonitrile. The ${ }^{11}$ B NMR spectrum of each of 7 $(-19.89)$ and $8(-19.78)$ exhibits a broad resonance, which is $c a .10 \mathrm{ppm}$ downfield compared to that of 3 and 4 . The molecular structure of 8 is shown in Fig. 2. The $\mathrm{BH}_{2} \mathrm{BH}_{2}$ core features two $3 \mathrm{c}-2 \mathrm{e}$ bonds with the $\mathrm{B} \cdots \mathrm{B}$ distance of $1.755 \AA$. This is actually similar to $\mathrm{B} \cdots \mathrm{B}$ distances in cationic (NHC) $\mathrm{BH}_{2}{ }^{6 b}$ as well as in neutral $\mathrm{RBH}_{2}$ dimers. ${ }^{23}$ Similarly, the $\mathrm{B} \cdots \mathrm{B}$ distance in 8 is consistent with that of the parent $\mathrm{B}_{2} \mathrm{H}_{6}$ determined by electron diffraction $(1.77 \AA)^{24}$ or X-ray methods (1.78-1.79 $\AA$ ). ${ }^{25}$

The exact location of the B-H hydrogen is uncertain due to the experimental restrictions. Nevertheless, DFT(M06-2X/def2SVP) optimized structures present a reasonable agreement with the experimental structure (Fig. 2). The theoretically pre-
dicted $\mathrm{B}-\mathrm{H}$ bond lengths are longer than the experimental values, which is a feature commonly observed between solidstate and theoretical structures which refer to isolated molecules. ${ }^{26}$ The experimentally observed $\mathrm{B}-\mathrm{B}$ distances are well represented by DFT calculations. The short B…B distances possibly indicate a weak bond. In fact, the B-B Wiberg Bond Indices (WBO in Table 1) are 0.64 au and 0.65 au for compounds 7 and 8, respectively. The increase in the bond order comes from the significantly shorter B-B distances in the dications. In this case, NBO calculations revealed the occurrence of two $\mathrm{B}-\mathrm{H}-\mathrm{B} 3 \mathrm{c}-2 \mathrm{e}$ bonds in the $\mathrm{HB}(\mu-\mathrm{H})_{2} \mathrm{BH}$ moiety where $43 \%$ is located at the H bridges and $\sim 28 \%$ at each boron atom (Tables S4 and $\mathrm{S} 5 \ddagger$ ). The NHO ligands have a C-B $\sigma$-bond where the polarization towards carbon is slightly lower $(65 \%$ for 7 and 8) than that in 5 and $\mathbf{6}$. The calculated charge distribution for the latter di-cationic species suggests that a positive charge of roughly +1.5 e resides at the NHO ligands. The somewhat counter intuitive charge at the boron atom can be rationalized in terms of the donor-acceptor bonding model ${ }^{27}$ which has successfully been used to explain the structure of boron compounds ${ }^{3 m, 28}$ and to predict new boron molecules with unusual bonding situations. ${ }^{3 k, 30,29}$ Compounds $5-8$ may be formally considered as complexes where a charged central

9: $\left[\left(\mathrm{L}^{2}\right)_{2} \mathrm{BH}_{2}\right] \mathrm{NTf}_{2}$
Scheme 4 Reaction of 8 with $L^{2}$ to boronium ion 9.
boron fragment $\left(\mathrm{B}_{2} \mathrm{H}_{5}{ }^{+}\right.$in the mono-cations and $\mathrm{B}_{2} \mathrm{H}_{4}{ }^{2+}$ in the di-cations) serves as an acceptor and the NHOs serve as donors, NHO $\rightarrow \mathrm{B}_{2} \mathrm{H}_{n}{ }^{q} \leftarrow$ NHO. The strong charge donation leads to negative charges at boron in the cations 5 and 6 and to rather small positive charges in the di-cations 7 and 8. A negative partial charge was previously found at the $\mathrm{BH}_{2}{ }^{+}$fragment in the cations $\left(\mathrm{L} \rightarrow \mathrm{BH}_{2} \leftarrow \mathrm{~L}\right]^{+}$. ${ }^{3 m}$

Treatment of 8 with two equivalents of the NHO ( $\mathrm{L}^{2}$ ) leads to the clean formation of a boronium compound $\left[\left(\mathrm{L}^{2}\right)_{2} \mathrm{BH}_{2}\right]$ [ $\mathrm{NTf}_{2}$ ] (9) (Scheme 4). The ${ }^{11}$ B NMR spectrum of 9 shows a broad signal at $\delta-23.8 \mathrm{ppm}$. While hydrogen atoms of the $\mathrm{BH}_{2}$ group could not be located, the ${ }^{1} \mathrm{H}$ NMR spectrum of compound 9 exhibits a remarkably up-field signal ( $\delta 0.34 \mathrm{ppm}$ ) for methylene $\left(\mathrm{CH}_{2} \mathrm{BH}_{2}\right)$ protons, which has been confirmed by a ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$-HSQC (heteronuclear single quantum coherence) experiment. Colourless crystals of 9 were obtained from a solution of dichloromethane $/ n$-hexane $(4: 1)$ at room temperature. The molecular structure of 9 features a $\mathrm{CH}_{2} \mathrm{BH}_{2} \mathrm{CH}_{2}$ moiety with the C-B-C angle of $109.22^{\circ}$ (Fig. 3). The C-B bond distance of $1.69 \AA$ is comparable to that of 8 .

Compounds 3-9 exhibit characteristic absorption bands for the terminal $\nu(\mathrm{B}-\mathrm{H})$ stretching vibrations from 2230 to $2463 \mathrm{~cm}^{-1}$. IR absorption bands in the $1561-1594 \mathrm{~cm}^{-1}$ region may be assigned for the bridging $\nu(\mathrm{B}-\mathrm{H})$ vibrations. ${ }^{30}$

Fig. 3 Molecular structure of compound 9. Hydrogen atoms except those on the $\mathrm{BH}_{2}$ moiety, isopropyl groups as well as the anionic part have been omitted for clarity. Thermal ellipsoids are represented the $50 \%$ probability level. Boron bound hydrogen atoms were refined without restraints. Selected experimental and theoretical [M06-2X/def2SVP] bond lengths [Å] and the bond angle [ ${ }^{\circ}$ ]: B1-C2 1.689(3) [1.693], B1-C32 1.690(3) [1.694], B1-H1 1.12(2) [1.226], B1-H2 1.12(2) [1.226], C2-C3 1.456(3) [1.455], C32-C33 1.459(3) [1.455], C2-B1-C32 109.2(2) [109.2], C3-C2-B1 111.9(2) [107.8], C33-C32-B1 110.5(2) [107.6].

## Experimental

All syntheses and manipulations were carried out under an inert atmosphere of dry argon or nitrogen gas using Schlenk line techniques and a glove box. $\mathrm{CD}_{2} \mathrm{Cl}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, o-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{D}_{4}$ and $o-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}$ (over $\mathrm{CaH}_{2}$ ), $\mathrm{C}_{6} \mathrm{D}_{6}$ and THF (over K-benzophenone ketyl) were dried and distilled under a dry argon atmosphere prior to use. All other solvents were dried and purified
by using a MBRAUN solvent purification system (MB SPS 800). ${ }^{1} \mathrm{H},{ }^{11} \mathrm{~B}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded using a Bruker Avance III 300 or a Bruker Avance DRX 500 spectrometer. ESI mass spectra were recorded with a Bruker micrOTOF or a Bruker maXis spectrometer. Melting points were measured with a Büchi Melting Point B-540 apparatus. Elemental analyses were performed at the Institute for Inorganic Chemistry, Universität Göttingen. (THF) $\mathrm{BH}_{3}$ (Aldrich) and $\mathrm{HNTf}_{2}$ (Aldrich) were used without further purification. $\mathrm{SIPrCH}_{2}\left(\mathrm{~L}^{1}\right)$ (1) and $\mathrm{IPrCH}_{2}\left(\mathrm{~L}^{2}\right)(2)$ were prepared by adopting the reported methods. ${ }^{14 b, 31}$

## Synthesis and characterization of compounds 3-9

$\left(\mathbf{L}^{\mathbf{1}}\right) \mathbf{B H}_{3}$ (3). A 1 M THF solution of (THF) $\mathrm{BH}_{3}(3.6 \mathrm{~mL}$, 3.60 mmol ) was added to an $n$-hexane solution of $\mathrm{L}^{1}$ (1) $(1.44 \mathrm{~g}, 3.57 \mathrm{mmol})$ at room $\left(25{ }^{\circ} \mathrm{C}\right)$ temperature. The resulting white slurry was stirred for 4 h . Filtration through a glass frit afforded a white solid, which was washed with $20 \mathrm{~mL} n$-hexane and dried under vacuum to yield $3(1.34 \mathrm{~g}, 90 \%)$. Colorless crystals of 2 were grown from a $20 \mathrm{~mL} \mathrm{CH} \mathrm{Cl}_{2} / n$-hexane ( $1: 1$ ) solution. Mp.: $201{ }^{\circ} \mathrm{C}$. MS (ESI, $m / z[\mathrm{M}]$ ): $415.33[\mathrm{M}-\mathrm{H}]^{+}$, 416.33 [M] ${ }^{\dagger}$. Elemental analysis for $\mathrm{C}_{28} \mathrm{H}_{41} \mathrm{~N}_{2} \mathrm{~B}$ (416): C 80.75, H 9.92, N 6.73; found C 80.44 , H 9.85, N 6.68. ## Crystallographic details

Suitable single crystals were selected from the mother liquor under Schlenk conditions and covered with perfluorinated polyether oil on a microscope slide, which was cooled under a nitrogen gas flow using the X-Temp2 device. ${ }^{32}$ The diffraction data of compounds 5,8 and 9 were collected at 100 K on a Bruker D8 three circle diffractometer, equipped with a SMART APEX II CCD detector and an INCOATEC microfocus source ( $\mathrm{Ag} \mathrm{K}_{\alpha}$ radiation) with INCOATEC Quazar mirror optics (Table 2). The diffraction data of compound 4 were collected at 100 K on a Bruker D8 three-circle diffractometer, equipped with a SMART APEX II CCD detector and an INCOATEC microfocus source (Mo K ${ }_{\alpha}$ radiation) with INCOATEC Quazar mirror optics. The data were integrated with SAINT ${ }^{33}$ and a multi-scan absorption correction with SADABS $^{34}$ was applied. The structure solution was performed with SHELXT ${ }^{35}$ and structure refinement was performed with SHELXL, ${ }^{36}$ using the graphical user interface SHELXLE. ${ }^{37}$ All non-hydrogen atoms were

refined with anisotropic displacement parameters. All hydrogen atoms, except those bound to boron atoms, were assigned to ideal positions and refined using a riding model with $U_{\text {iso }}$ constrained to 1.2 (1.5) times the $U_{\text {eq }}$ value of the parent carbon atom. The positions of boron bound hydrogen atoms were found by difference Fourier analysis and the positions were refined.

## Computational details

The geometries of compounds 5-9 have been optimized using the functional M06-2X ${ }^{20 a}$ combined with the def2-SVP basis set. ${ }^{20 b}$ Stationary points were located with the Berny algorithm ${ }^{38}$ using redundant coordinates. Analytical Hessians were computed to determinate the nature of the stationary points. ${ }^{39}$ All geometry optimizations were performed using the Gaussian 09 suite of programs. ${ }^{40}$ The $\mathrm{NBO}^{21,22,41}$ analyses have been carried out with the GENNBO $5.9^{42}$ program at the M06-2X/ def2-TZVPP level of theory.

## Conclusions

In conclusion, mono-cationic $\left[\left\{\left(\mathrm{L}^{1}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf}_{2}\right)(5)$ and $\left[\left\{\left(\mathrm{L}^{2}\right) \mathrm{BH}_{2}\right\}_{2}(\mu-\mathrm{H})\right]\left(\mathrm{NTf}_{2}\right)$ (6) and di-cationic $\left[\left\{\left(\mathrm{L}^{1}\right) \mathrm{BH}\right\}_{2}(\mu-\mathrm{H})_{2}\right]-$ $\left(\mathrm{NTf}_{2}\right)_{2}(7)$ and $\left[\left\{\left(\mathrm{L}^{2}\right) \mathrm{BH}\right\}_{2}(\mu-\mathrm{H})_{2}\right]\left(\mathrm{NTf}_{2}\right)_{2}(8)$ hydrido boron compounds are readily accessible by a hydride abstraction reaction of 3 and 4 with a commercially available Brønsted acid. Structure and bonding of these compounds featuring $\mathrm{CH}_{2} \mathrm{BH}_{2}(\mu-\mathrm{H})-$ $\mathrm{BH}_{2} \mathrm{CH}_{2}\left(5\right.$ and 6 ) and $\mathrm{CH}_{2} \mathrm{BH}(\mu-\mathrm{H})_{2} \mathrm{BHCH}_{2}(7$ and 8$)$ scaffolds have been analysed using experimental and theoretical methods. The NHO ligand forms a $\mathrm{C}-\mathrm{B} \sigma$-bond, where the polarization towards carbon is slightly lower ( $65 \%$ for 7 and 8 ) than that for 5 and 6. NBO calculations revealed the occurrence of two $\mathrm{B}-\mathrm{H}-\mathrm{B} 3 \mathrm{c}-2 \mathrm{e}$ bonds in the $\mathrm{HB}(\mu-\mathrm{H})_{2} \mathrm{BH}$ moiety where $43 \%$ is located at the H bridges and $\sim 28 \%$ at each boron atom.

Crystallographic data of compounds 4,5,8 and 9 have been deposited with the Cambridge Crystallographic Data Centre.

## Acknowledgements

We are thankful to the Deutsche Forschungsgemeinschaft (DFG) (GH 129/4-1) for financial support.
